Highly-efficient, regulated dual-output, ambient energy manager
for AC or DC sources with optional primary battery

Features

Ultra-low-power start-up:
- Cold start from 380 mV input voltage and 3 μW input power (typical)
- RF input power from -18.5 dBm up to 10 dBm (typical)

Ultra-low-power boost regulator:
- Open-circuit voltage sensing for MPPT every 0.33 s
- Configurable MPPT with 2-pin programming
- Selectable Voc ratios of 50, 65 or 80 %
- Input voltage operation range from 50 mV to 5 V
- MPPT voltage operation range from 50 mV to 5 V
- Constant impedance matching (ZMPPT)

Integrated 1.2/1.8 V LDO regulator:
- Up to 20 mA load current
- Power gated dynamically by external control
- Selectable output voltage

Integrated 1.8 V-4.1 V LDO regulator:
- Up to 80 mA load current with 300 mV drop-out
- Power gated dynamically by external control
- Selectable or adjustable output voltage

Flexible energy storage management:
- Selectable overcharge and overdischarge protection for any type of rechargeable battery or (super)capacitor
- Fast supercapacitor charging
- Warns the load when battery is running low
- Warns when output voltage regulators are available

Smallest footprint, smallest BOM:
- Only seven passive external components

Optional primary battery:
- Automatically switches to the primary battery when the secondary battery is exhausted

Integrated balun for dual-cell supercapacitor

Description

The AEM30940 is an integrated energy management circuit that extracts DC power from a piezo generator, a micro turbine generator or any high frequency RF input to simultaneously store energy in a rechargeable element and supply the system with two independent regulated voltages. The AEM30940 allows to extend battery lifetime and ultimately eliminates the primary energy storage element in a large range of wireless applications such as industrial monitoring, home automation, transportation and smart agriculture.

The AEM30940 harvests the available input current up to 110 mA. It integrates an ultra-low power boost converter to charge a storage element, such as a Li-ion battery, a thin film battery, a supercapacitor or a conventional capacitor. The boost converter operates with input voltages in a range from 50 mV to 5 V. With its unique cold-start circuit, it can start operating with empty storage elements at an input voltage as low as 380 mV and an input power of just 3 μW.

The low-voltage supply typically drives a microcontroller at 1.2 V or 1.8 V. The high-voltage supply typically drives a radio transceiver at a configurable voltage between 1.8 V and 4.1 V. Both are driven by highly-efficient LDO (Low Dropout) regulators for low noise and high stability.

Configuration pins determine various operating modes by setting predefined conditions for the energy storage element (overcharge or overdischarge voltages), and by selecting the voltage of the high-voltage supply and the low-voltage supply. Moreover, special modes can be obtained at the expense of a few configuration resistors.

The chip integrates all the active elements for powering a typical wireless sensor. Five capacitors and two inductors are required, available in the small 0402 and 0603 size, respectively. With only seven external components, integration is maximum, footprint and BOM are minimum, optimizing the time-to-market and the costs of WSN designs.

Applications

- Piezo harvesting
- Micro turbine harvesting
- RF harvesting
- Industrial monitoring
- Home automation
- Transportation
- Smart agriculture

1 Introduction

The AEM30940 is a full-featured energy efficient power management circuit able to charge a storage element (battery or supercapacitor, connected to BATT) from an energy source (connected to SRC) as well as to supply loads at different operating voltages through two power supplying LDO regulators (LVOUT and HVOUT).

The heart of the AEM30940 is a cascade of two regulated switching converters, namely the boost converter and the buck converter with high-power conversion efficiencies (See Page 18).

At first start-up, as soon as a required cold-start voltage of 380 mV and a scant amount of power of just 3 µW available from the harvested energy source, the AEM coldstarts. After the cold start, the AEM can extract the power available from the source as long as the input voltage is comprised between 50 mV and 5 V.

Through three configuration pins (CFG[2:0]), the user can select a specific operating mode from a range of seven modes that cover most application requirements without any dedicated external component. Those operating modes define the LDO output voltages and the protection levels of the storage element. Note that a custom mode allows the user to define his own storage element protection levels and the output voltage of the high-voltage LDO (See Page 11).

The Maximum Power Point (MPP) ratio can be configured using two configuration pins (SELMPP[1:0]) (See Page 12).

Two logic control pins are provided (ENLV and ENHV) to dynamically activate or deactivate the LDO regulators that supply the low- and high-voltage load, respectively. The status pin STATUS[0] alerts the user that the LDOs are operational and can be enabled. This signal can also be used to enable an optional external regulator.

If the battery voltage gets depleted, the LDOs are power gated and the controller is no longer supplied by the storage element to protect it from further discharge. Around 600 ms before the shutdown of the AEM, the status pin STATUS[1] alerts the user for a clean shutdown of the system.

However, if the storage element gets depleted and an optional primary battery is connected on PRIM, the chip automatically uses it as a source to recharge the storage element before switching back to the ambient source. This guarantees continuous operation even under the most adverse conditions (See Page 10). STATUS[1] is asserted when the primary battery is providing power.

The status of the MPP controller is reported with one dedicated status pin (STATUS[2]). The status pin is asserted when a MPP calculation is being performed.

ESD CAUTION

ESD (ELECTROSTATIC DISCHARGE) SENSITIVE DEVICE

These devices have limited built-in ESD protection and damage may thus occur on devices subjected to high-energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

6 Functional Block Diagram

Figure 3: Functional block diagram
7 Theory of Operation

7.1 Deep sleep & Wake up modes

The **DEEP SLEEP MODE** is a state where all nodes are deeply discharged and there is no available energy to be harvested. As soon as the required cold-start voltage of 380 mV and a sparse amount of power of just 3 µW becomes available on **SRC**, the **WAKE UP MODE** is activated. **Vboost** and **Vbuck** rises up to a voltage of 2.2 V. **Vboost** then rises alone up to **Vovch**. At that stage, both LDOs are internally deactivated. Therefore, **STATUS[0]** is equal to 0 as shown in Figure 9 and Figure 10.

When **Vboost** reaches **Vovch**, two scenarios are possible: in the first scenario, a super-capacitor or a capacitor having a voltage lower than **Vchrdy** is connected to the **BATT** node. In the second scenario, a charged battery is connected to the **BATT** node.

**Table 6**: Minimum input power for the cold start (typical). Results obtained with the matching network and rectifier designed by e-peas

**Supercapacitor as a storage element**

If the storage element is a supercapacitor, the storage element may need to be charged from 0 V. The boost converter charges **BATT** from the input source and by modulating the conductance of M2. During the charge of the **BATT** node, both LDOs are deactivated and **STATUS[0]** is de-asserted. When **Vbatt** reaches **Vchrdy**, the circuit enters **NORMAL MODE**, **STATUS[0]** is asserted and the LDOs can be activated by the user using the **ENLV** and **ENHV** control pins as shown in Figure 9.

**Battery as a storage element**

If the storage element is a battery, but its voltage is lower than **Vchrdy**, then the storage element first needs to be charged until it reaches **Vchrdy**. Once **Vbatt** exceeds **Vchrdy**, or if the battery was initially charged above **Vchrdy**, the circuit enters **NORMAL MODE**. **STATUS[0]** is asserted and the LDOs can be activated by the user thanks to **ENLV** and **ENHV** as shown in Figure 10.

![Figure 4: Simplified schematic view of the AEM30940](image)

![Figure 5: Diagram of the AEM30940 modes](image)
7.2 Normal mode

Once the AEM enters NORMAL MODE, three scenarios are possible:

- There is enough power provided by the source to maintain Vbatt above Vovdis but Vbatt is below Vovch. In that case, the circuit remains NORMAL MODE.
- The source provides more power than the load consumes, and Vbatt increases above Vovch, the circuit enters into the OVERVOLTAGE MODE, as explained in the Over-voltage mode section.
- Due to a lack of power from the source, Vbatt falls below Vovdis. In this case, either the circuit enters SHUTDOWN MODE as explained in Shutdown mode section or, if a charged primary battery is connected on PRIM, the circuit enters PRIMARY MODE as explained in the Primary mode section.

Matching network and rectifier

To connect AC sources to the AEM30940, an external rectifier is required as well as a matching network in the case RF energy harvesting. The objective of the matching network is to modify the impedance relationship between the RF source and the rectifier in order to optimize the power transfer over a frequency band and an input power range. For RF applications, external high frequency rectifiers as well as matching networks are available for the following RF bands: 828 MHz, 915 MHz, 945 MHz (GSM900), 1.84 GHz (GSM1800), 2.11 GHz (3G), 2.45 GHz (WiFi).

Boost

The boost (or step-up) converter raises the voltage available at BUFSRC to a level suitable for charging the storage element, in the range of 2.2 V to 4.5 V, according to the system configuration. This voltage (Vboost) is available at the BOOST pin. The switching transistors of the boost converter are M3 and M4, with the switching node available externally at SW-BOOST. The reactive power components of this converter are the external inductor and capacitor LBOOST and CBOOST. Periodically, the MPP control circuit disconnects the source from the BUFSRC pin with the transistor M1 in order to measure the open-circuit voltage of the harvester on SRC and define the optimal level of voltage. BUFSRC is decoupled by the capacitor CSRC, which smooths the voltage against the current pulses induced by the boost converter. The storage element is connected to the BATT pin, at a voltage Vbatt. This node is linked to BOOST through the transistor M2. In NORMAL MODE, this transistor effectively shorts the battery to the BOOST node (Vbatt = Vboost). When energy harvesting is occurring, the boost converter delivers a current that is shared between the battery and the loads. M2 is opened to disconnect the storage element when Vbatt reaches Vovdis. However, in such a scenario, the AEM30940 offers the possibility of connecting a primary battery to recharge Vbatt up to the Vchrdy. The transistor M9 connects PRIM to BUF-SRC and the transistor M1 is opened to disconnect the SRC input pin as explained in the Primary mode section and shown in Figure 13.

Buck

The buck (or step-down) converter lowers the voltage from Vboost to a constant Vbuck value of 2.2 V. This voltage is available at the BUCK pin. The switching transistors of the buck converter are M5 and M6, with the switching node available externally at SWBUCK. The reactive power components of the buck converter are the external inductor LBUCK and the capacitor CBUCK.

LDO outputs

Two LDOs are available to supply loads at different operating voltages:

Through M7, Vboost supplies the high-voltage LDO that powers its load through HVOUT. This regulator delivers a clean voltage (Vhv) with a maximum current of 80 mA on HVOUT. In the built-in configuration modes, an output voltage of 1.8 V, 2.5 V or 3.3 V can be selected. In the custom configuration mode, it is adjustable between 2.2 V and Vbatt-0.3 V. The high-voltage output can be dynamically enabled or disabled with the logic control pin ENHV. The output is decoupled by the external capacitor CHV.

Through M8, Vbuck supplies the low-voltage LDO that powers its load through LVOUT. This regulator delivers a clean voltage (Vvl) of 1.8 V or 1.2 V with a maximum current of 20 mA on LVOUT. The low-voltage output can be dynamically enabled or disabled with the logic control pin ENLV. The output is decoupled by the external capacitor CLV.

Status pin STATUS[0] alerts the user when the LDOs can be enabled as explained in the Deep sleep & Wake up modes section and in the Shutdown mode section. The table below shows the four possible configurations:

Table 7: LDOs configurations

7.3 Overvoltage mode

When Vbatt reaches Vovch, the charge is complete and the internal logic maintains Vbatt around Vovch with a hysteresis of a few mV as shown in Figure 11 to prevent damage to the storage element and to the internal circuitry. In this configuration, the boost converter is periodically activated to maintain Vbatt and the LDOs are still available. Moreover, when the boost converter is not activated, the transistor M1 in Figure 4 is opened to prevent current from the source to the storage element when Vsrc is higher than Vovch.

---

1Contact support@e-peas.com for additional information
7.4 Primary mode
When \( V_{\text{batt}} \) drops below \( V_{\text{ovdis}} \), the circuit compares the voltage on \( \text{PRIM} \) with the voltage on \( \text{FB}_{\text{PRIM} \text{J}} \) to determine whether a charged primary battery is connected on \( \text{PRIM} \). The voltage on \( \text{FB}_{\text{PRIM} \text{J}} \) is set thanks to two optional resistances as explained in the Primary battery configuration section. If the voltage on \( \text{PRIM} \) divided by 4 is higher than the voltage on \( \text{FB}_{\text{PRIM} \text{J}} \), the circuit enters PRIMARY MODE as shown in Figure 13.
In that mode, transistor M1 is opened and the primary battery is connected to \( \text{BUFFSRC} \) through transistor M9 to become the source of energy for the AEM30940. The chip remains in this mode until \( V_{\text{batt}} \) reaches \( V_{\text{chrdy}} \). When \( V_{\text{batt}} \) reaches \( V_{\text{chrdy}} \), the circuit enters NORMAL MODE. As long as the chip is in PRIMARY MODE, STATUS[1] is asserted.

If no primary battery is used in the application, \( \text{PRIM}, \text{FB}_{\text{PRIM} \text{J}} \) and \( \text{FB}_{\text{PRIM} \text{D}} \) must be tied to \( \text{GND} \).

7.5 Shutdown mode
When \( V_{\text{batt}} \) drops below \( V_{\text{ovdis}} \) and no power is available from a primary battery, the circuit enters SHUTDOWN MODE as shown in Figure 12 to prevent deep discharge potentially leading to damage to the storage element and instability of the LDOs. The circuit asserts STATUS[1] to warn the system that a shutdown will occur. Both LDO regulators remain enabled.

If no primary battery is used, this allows the load, whether it is powered on \( \text{LVOUT} \) or \( \text{HVOUT} \), to be interrupted by the low-to-high transition of STATUS[1], and to take all appropriate actions before power shutdown.

If energy at the input source is available and \( V_{\text{batt}} \) recovers to \( V_{\text{chrdy}} \) within \( T_{\text{crit}} \) (~ 600 ms), the AEM returns in NORMAL MODE. But if, after \( T_{\text{crit}}, \) \( V_{\text{batt}} \) does not reach \( V_{\text{chrdy}} \), the circuit enters DEEP SLEEP MODE. The LDOs are deactivated and \( \text{BATT} \) is disconnected from \( \text{BOOST} \) to avoid damaging the battery due to the overdischarge. From now, the AEM will have to go through the wake-up procedure described in the Deep sleep & Wake up modes section.

7.6 Maximum power point tracking
During NORMAL MODE, SHUTDOWN MODE and a part of WAKE UP MODE, the boost converter is regulated thanks to an internal MPPT (Maximum Power Point Tracking) module. \( V_{\text{mpp}} \) is the voltage level of the MPP, and depends on the input power available at the source. The MPPT module evaluates \( V_{\text{mpp}} \) as a given fraction of \( V_{\text{src}} \), the open-circuit voltage of the source. By temporarily disconnecting the source from \( \text{CSRC} \) as shown in Figure 4 for 5.12 ms, the MPPT module receives from and maintains knowledge of \( V_{\text{mpp}} \). This sampling occurs approximatively every 0.33 s.

With the exception of this sampling process, the voltage across the source, \( V_{\text{src}} \), is continuously compared to \( V_{\text{mpp}} \). When \( V_{\text{src}} \) exceeds \( V_{\text{mpp}} \) by a small hysteresis, the boost converter is switched on, extracting electrical charges from the source and lowering its voltage. When \( V_{\text{src}} \) falls below \( V_{\text{mpp}} \) by a small hysteresis, the boost converter is switched off, allowing the harvester to accumulate new electrical charges into \( \text{CSRC} \), which restores its voltage. In this manner, the boost converter regulates its input voltage so that the electrical current (or flow of electrical charges) that enters the boost converter yields the best power transfer from the harvester under any ambient conditions. The AEM30940 supports any \( V_{\text{mpp}} \) level in the range from 0.05 V to 5 V. It offers a choice of four values for the \( V_{\text{mpp}}/V_{\text{src}} \) fraction or to match the input impedance of the BOOST converter with an impedance connected to the ZMPP terminal through configuration pins \( \text{SELMPP}[1:0] \) as shown in Table 9. The status of the MPPT controller is reported through one dedicated status pins (STATUS[2]). The status pin is asserted when a MPP calculation is being performed.

7.7 Balun for dual-cell supercapacitor
The balun circuit allows users to balance the internal voltage in a dual-cell supercapacitor in order to avoid damaging the super-capacitor because of excessive voltage on one cell. If \( \text{BAL} \) is connected to \( \text{GND} \), the balun circuit is disabled. This configuration must be used if a battery, a capacitor or a single-cell supercapacitor is connected on \( \text{BATT} \). If \( \text{BAL} \) is connected to the node between the cells of a supercapacitor, the balun circuit compensates for any mismatch of the two cells that could lead to over-charge of one of both cells. The balun circuit ensures that \( \text{BAL} \) remains close to \( V_{\text{batt}}/2 \). This configuration must be used if a dual-cell supercapacitor is connected on \( \text{BATT} \).

Table 8: Usage of CFG[2:0]

8.1 Battery and LDOs configuration

Through three configuration pins (CFG[2:0]), the user can set a particular operating mode from a range that covers most application requirements, without any dedicated external component as shown in Table 8. The three threshold levels are defined as:

- **Vovch**: Maximum voltage accepted on the storage element before disabling the boost converter,
- **Vchrdy**: Minimum voltage required on the storage element after a cold start before enabling the LDOs,
- **Vovdis**: Minimum voltage accepted on the storage element before considering the storage element as depleted.

See **Theory of Operation** section for more information about the purposes of these thresholds.

The two LDOs output voltages are called **Vhv** and **Vlv** for the high- and low-output voltages, respectively. In the built-in configuration mode, seven combinations of these voltage levels are hardwired and selectable through the CFG[2:0] configuration pins, covering most application cases. When a predefined configuration is selected, the resistor pins dedicated to a custom configuration should be left floating (SET_OVDIS, SET_CHRDY, SET_OVCH, FB_HV).

A custom mode allows the user to define the **Vovch**, **Vchrdy**, **Vovdis** and **Vhv** threshold voltages.

**Custom mode**

When CFG[2:0] are tied to GND, the custom mode is selected and all six configuration resistors shown in Figure 6, must be wired as follows:

- **Vovch**, **Vchrdy** and, **Vovdis** are defined thanks to R1, R2, R3 and R4. If we define the total resistor (R1 + R2 + R3 + R4) as **RT**, R1, R2, R3, and R4 are calculated as:
  - **R1** = **RT**(1 V/Vovch)
  - **R2** = **RT**(1 V/Vchrdy - 1 V/Vovch)
  - **R3** = **RT**(1 V/Vovdis - 1 V/Vchrdy)
  - **R4** = **RT**(1 - 1 V/Vovdis)

**Vhv** is defined thanks to R5 and R6. If we define the total resistor (R5 + R6) as **RV**, R5 and R6 are calculated as:

- **R5** = **RV**(1 V/Vhv)
- **R6** = **RV**(1 - 1 V/Vhv)

The resistors should have high values to make the additional power consumption negligible. Moreover, the following constraints must be adhered to ensure the functionality of the chip:

- **Vchrdy** + 0.05 V ≤ **Vovch** ≤ 4.5 V
- **Vovdis** + 0.05 V ≤ **Vchrdy** ≤ **Vovch** - 0.05 V
- 2.2 V ≤ **Vovdis**
- **Vhv** ≤ **Vovdis** - 0.3 V

![Figure 6: Custom configuration resistors](image)
8.2 MPPT configuration

Two dedicated configuration pins, SELMPP[1:0], allow selecting the MPP tracking ratio based on the characteristic of the input power source.

</tbody>
</table>

Table 9: Usage of SELMPP[1:0]

8.3 Primary battery configuration

To use the primary battery, it is mandatory to determine $V_{prim\_min}$, the voltage of the primary battery at which it has to be considered as empty. During the evaluation of $V_{prim\_min}$, the circuit connects $FB_{PRIM\_D}$ to GND. The circuit uses a resistive divider between $BUCK$ and $FB_{PRIM\_D}$ to define the voltage on $FB_{PRIM\_U}$ as $V_{prim\_min}$ divided by 4.

When $V_{prim\_min}$ is not evaluated, $FB_{PRIM\_D}$ is left floating to avoid quiescent current on the resistive divider. If we define the total resistor ($R_7 + R_8$) as $RP$, $R_7$ and $R_8$ are calculated as:

- $100 \text{k} \Omega \leq RP \leq 500 \text{k} \Omega$
- $R_7 = \frac{V_{prim\_min}}{4} \frac{1}{RP} / 2.2 \text{V}$
- $R_8 = RP - R_7$

Note that $FB_{PRIM\_U}$ and $FB_{PRIM\_D}$ must be tied to GND if no primary battery is used.

8.4 ZMPPT configuration

Instead of working at a ratio of the open-circuit voltage, the AEM30940 can regulate the input impedance of the BOOST converter so that it matches a constant impedance connected to the $ZMPP$ pin ($R_{ZMPP}$). In this case, the AEM30940 regulates $V_{src}$ at a voltage equals to the product of the $ZMPP$ impedance and the current available at the $SRC$ input.

- $10 \Omega \leq R_{ZMPP} \leq 1 \text{M} \Omega$

8.5 No-battery configuration

If the harvested energy source is permanently available and covers the application purposes or if the application does not need to store energy when the harvested energy source is not available, the storage element may be replaced by an external capacitor $CBATT$ of minimum 150 μF.

8.6 Storage element information

The energy storage element of the AEM30940 can be a rechargeable battery, a supercapacitor or a large capacitor (minimum 150 μF). It should be chosen so that its voltage does not fall below $V_{ovdis}$ even during occasional peaks of the load current. If the internal resistance of the storage element cannot sustain this voltage limit, it is advisable to buffer the battery with a capacitor.

The $BATT$ pin that connects the storage element must never be left floating. If the application expects a disconnection of the battery (e.g. because of a user removable connector), the PCB should include a capacitor of at least 150 μF. The leakage current of the storage element should be small as leakage currents directly impact the quiescent current of the subsystem.

**External inductors information**

The AEM30940 operates with two standard miniature inductors of 10 μH. $L_{BOOST}$ and $L_{BUCK}$ must respectively sustain a peak current of at least 250 mA and 50 mA and a switching frequency of at least 10 MHz. Low equivalent series resistance (ESR) favors the power conversion efficiency of the boost and buck converters.

**External capacitors information**

The AEM30940 operates with four identical standard miniature ceramic capacitors of 10 μF and one miniature ceramic capacitor of 22 μF. The leakage current of the capacitors should be small as leakage currents directly impact the quiescent current of the subsystem.

- **CSRC**
  This capacitor acts as an energy buffer at the input of the boost converter. It prevents large voltage fluctuations when the boost converter is switching. The recommended value is 10 μF +/- 20 %.
- **CBUCK**
  This capacitor acts as an energy buffer for the buck converter. It also reduces the voltage ripple induced by the current pulses inherent to the switched mode of the converter. The recommended value is 10 μF +/- 20 %.
- **CBOOST**
  This capacitor acts as an energy buffer for the boost converter. It also reduces the voltage ripple induced by the current pulses inherent to the switched mode of the converter. The recommended value is 22 μF +/- 20 %.

These capacitors ensure a high-efficiency load regulation of the high-voltage and low-voltage LDO regulators. Closed-loop stability requires the value to be in the range of 8 μF to 14 μF.
9 Typical Application Circuits

9.1 Example circuit 1

The energy source is a RF source, and the storage element is a standard Li-ion battery cell. The radio communication makes use of a transceiver that operates from a 3.3 V supply. A micro-controller supplied by a 1.8 V supply controls the application.

This circuit uses a pre-defined operating mode, typical of systems that use standard components for radio and energy storage.

The operating mode pins are connected to:
- \( \text{CFG}[2:0] = 111 \)

Referring to Table 8, in this mode, the threshold voltages are:
- \( V_{\text{ovch}} = 4.12 \text{ V} \)
- \( V_{\text{chrdy}} = 3.67 \text{ V} \)
- \( V_{\text{ovdis}} = 3.60 \text{ V} \)

Moreover, the LDOs output voltages are:
- \( V_{hv} = 3.3 \text{ V} \)
- \( V_{lv} = 1.8 \text{ V} \)

A primary battery is also connected as a back-up solution. The minimal level allowed on this battery is set at 3.5 V. Following equations on Page 12:
- \( R_P = 0.5 \text{ M}\Omega \)
- \( R_7 = \frac{(3.5 \text{ V} \times 0.5 \text{ M}\Omega)}{2.2 \text{ V}} = 200 \text{ k}\Omega \)
- \( R_8 = 0.5 \text{ M}\Omega \times 200 \text{ k}\Omega = 300 \text{ k}\Omega \)

The MPP configuration pins \( \text{SELMPP}[1:0] \) are tied to GND (logic low), selecting an MPP ratio of 50%.

The application software can enable or disable the radio transceiver with a GPIO connected to \( \text{ENHV} \).
9.2 Example circuit 2

The energy source is a piezo source, and the storage element is a dual-cell supercapacitor. The supercapacitor can be completely depleted during the cold start. Moreover, BAL is connected to the dual-cell supercapacitor to compensate for any mismatch between the two cells and in that way protect the supercapacitor.

A micro-controller pilots and collects information from a sensor. The operating mode pins are connected to:

- **CFG[2:0] = 000**

The user wants a custom configuration with **Vvch**, **Vchrdy** and **Vvdis** at 4.5 V, 4.2 V and 3.5 V, respectively. The user chooses 54 MΩ for **RT**. Following the equation in page 11:

- R1=54 MΩ\(\left(\frac{1}{\frac{3.5}{4.3}}\right)\)=12 MΩ
- R2=54 MΩ\(\left(\frac{1}{\frac{4.2}{4.5}}\right)\)=850 kΩ
- R3=54 MΩ\(\left(\frac{1}{\frac{3.5}{4.3}}\right)\)=2.57 MΩ

- R4=54 MΩ\(\left(1-\frac{1}{\frac{3.5}{4.3}}\right)\)=38.6 MΩ

In the custom mode, the **Vlv** equals 1.8 V and the application software can enable or disable the sensor with a GPIO connected to **ENLV**.

On **Vhv**, the user wants a 3.3 V voltage. As shown in page 11, the user chooses a resistor **RV** equal to 35 MΩ:

- R5=35 MΩ\(\left(\frac{1}{\frac{3.3}{3.5}}\right)\)=10.6 MΩ
- R6=35 MΩ\(\left(1-\frac{1}{\frac{3.3}{3.5}}\right)\)=24.4 MΩ

The **ENHV** enable pin for the high-voltage LDO is tied to BUCK. The microcontroller is enabled when **Vbatt** and **Vboost** exceeds **Vchrdy** as the high-voltage regulator supplies it.

The MPP configuration pins **SELMPP[1:0]** are tied to BUCK (logic high), selecting the ZMPPT configuration to match a 1 KΩ impedance.

No primary battery is connected and the **PRIM**, **FB_PRIM_U** and **FB_PRIM_D** pins are tied to GND.

Figure 12: Shutdown mode (without primary battery)
Figure 13: Switch to primary battery if the battery is overdischarged

CFG[2:0] = 3'b111, SELMPP[1:0] = 2'b10, Storage element: capacitor (4.85 mF), SRC: current source (1 mA) with voltage compliance (3 V), ENLV = 1'b1, ENHV = 1'b1, LVOUT load = 22 kΩ, HVOUT load = 22 kΩ, PRIM: voltage source (3 V) with current compliance (1 mA). R7 = 68 kΩ, R8 = 330 kΩ.
10 Performance Data

10.1 BOOST conversion efficiency

![Graph 1: Boost efficiency for Isrc at 100 µA, 1 mA, 10 mA and 100 mA](image1)

![Graph 2: Boost efficiency for Isrc at 100 µA, 1 mA, 10 mA and 100 mA](image2)

Figure 14: Boost efficiency for Isrc at 100 µA, 1 mA, 10 mA and 100 mA

10.2 Quiescent current

![Graph 3: Quiescent current with LDOs on and off](image3)

Figure 15: Quiescent current with LDOs on and off
10.3 High-voltage LDO regulation

Figure 16: HVOUT at 3.3 V and 2.5 V

10.4 Low-voltage LDO regulation

Figure 17: LVOUT at 1.2 V and 1.8 V
10.5 High-voltage LDO efficiency

![Graph 1: HVOUT efficiency at 1.8 V, 2.5 V and 3.3 V](image1)

Figure 18: HVOUT efficiency at 1.8 V, 2.5 V and 3.3 V

The theoretical efficiency of a LDO can be simply calculated as \( \frac{V_{out}}{V_{in}} \) if quiescent current can be neglected with regards to the output current. In the case of the high-voltage LDO, the theoretical efficiency is equal to \( \frac{V_{HV}}{V_{batt}} \).

10.6 Low-voltage LDO efficiency

![Graph 2: Efficiency of BUCK cascaded with LVOUT at 1.2 V and 1.8 V](image2)

Figure 19: Efficiency of BUCK cascaded with LVOUT at 1.2 V and 1.8 V

The theoretical efficiency of the low-voltage LDO is equal to \( \frac{V_{LV}}{V_{buck}} \). Starting from the battery, the efficiency of the buck converter has to be taken into account (see Figure 4). The efficiency between \( V_{batt} \) and \( V_{LV} \) is therefore equal to \( \eta_{buck} \).
10.7 RF path efficiency

The RF path efficiency is defined as the ratio between the power available at the output of the rectifier (SRC) and the power at the input of the matching network (50 Ω single input SMA).
10.8 Overall efficiency

![Overall efficiency graph](image)

Figure 26: Overall efficiency (RF path and boost converter) with VBOOST = 4.5 V

The overall efficiency is defined as the ratio between the power available at the output of the boost converter and the power at the input of the matching network (50 Ω single input SMA).
